

ABSTRACT OF THE DISCLOSURE

Method, system and computer-executable code are disclosed for synthesizing a representation of a circuit into a new circuit representation having greater unateness. The invention includes partitioning a circuit representation to
5 obtain a representation of at least one sub-circuit, recursively decomposing the representation of the at least one sub-circuit into a sum-of-products or product-of-sums representation having greater unateness than the representation of the at least one sub-circuit, merging the sum-of-products or product-of-sums representation into the circuit representation to form a new circuit representation, and repeating until
10 a desired level of unateness for the new circuit representation is achieved. Algebraic division is implemented to merge common expressions of the sum-of-products or product-of-sums representations. A zero-suppressed binary decision diagram is implemented to recursively decompose the representation of the sub-circuit.
